Acta Palaeontologica Polonica 55 (1), 2010: 73–84 doi: <http://dx.doi.org/10.4202/app.2009.0068>

The Campanian (Upper Cretaceous) seep carbonate at Omagari (Hokkaido, Japan) yields a monospecific association of the terebratulide brachiopod *Eucalathis methanophila* Bitner sp. nov. The association is the only occurrence of brachiopods known from the post–Early Cretaceous history of chemosynthesis–based communities. Unlike many earlier rhynchonellide–dominated hydrocarbon seep associations—which disappeared in Aptian times—this association is composed of chlidonophorid terebratulides. It is hypothesised here that large rhynchonellide brachiopods have been outcompeted from chemosynthesis–based associations by large chemosymbiotic bivalves (especially lucinids) and that this seep association containing numerous terebratulide brachiopods originated as a result of immigration from the background fauna settling in a seep that lacked numerous large bivalves but offered some hard substrates for brachiopod attachment. Some living chlidonophorids are known to settle around seep/vent localities or more generally in deep–water hard–substrate settings. We review occurrences of brachiopods in chemosynthesis–based associations and show that brachiopods immigrated repeatedly to seep/vent environments. *Eucalathis methanophila* Bitner sp. nov. represents the oldest and single Mesozoic record of the genus. The new species is similar in ornamentation to three living species, Indo–Pacific *E. murrayi*, eastern Atlantic *E. tuberosa*, and Caribbean *E. cubensis* but differs in having a higher beak and wider loop. Additionally the studied species is nearly twice as large as *E. tuberosa*.

Key words: Brachiopoda, Chlidonophoridae, *Eucalathis*, hydrocarbon seep, chemosynthesis-based community, Campanian, Cretaceous, Mesozoic, Japan.
