## SUPPLEMENTARY ONLINE MATERIAL FOR

### The teeth of the unenlagiine theropod *Buitreraptor* from the Cretaceous of Patagonia, Argentina, and the unusual dentition of the Gondwanan dromaeosaurids

Federico A. Gianechini, Peter J. Makovicky, and Sebastián Apesteguía

Published in *Acta Palaeontologica Polonica* 2011 56 (2): 279-290.

doi:10.4202/app.2009.0127

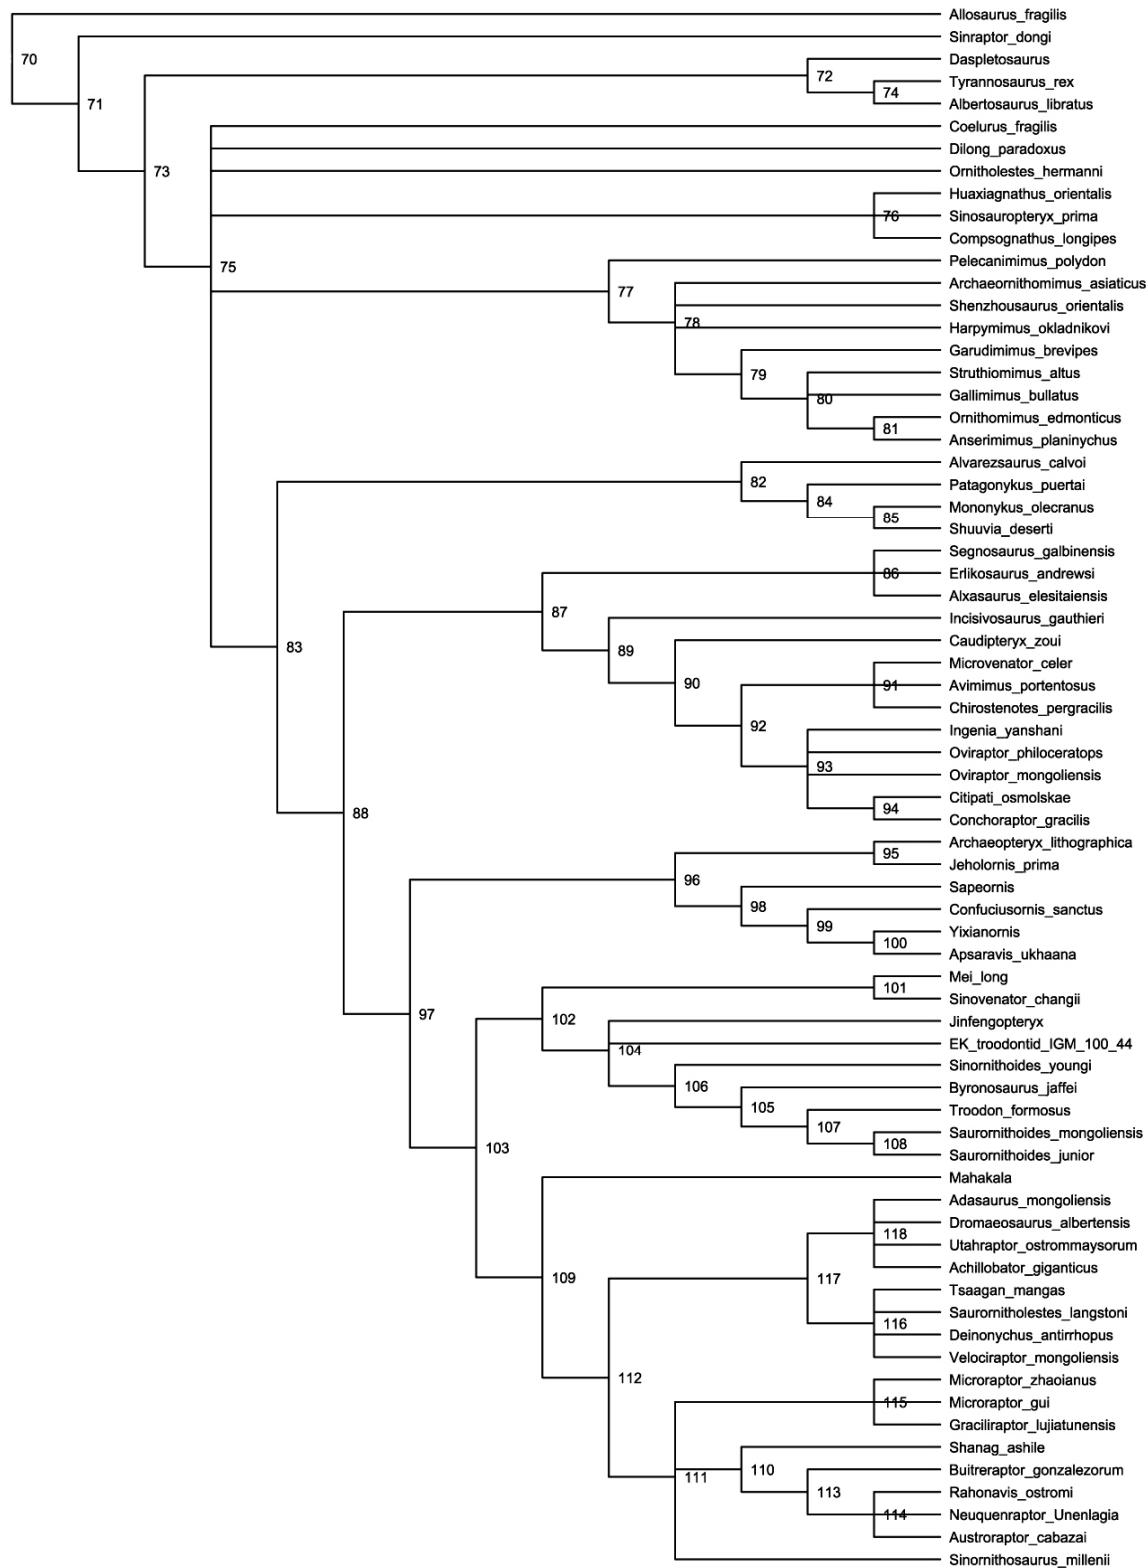

#### PHYLOGENETIC ANALYSIS

The phylogenetic analysis was performed using the recently published dataset of Turner et al. (2007), into which *Austroraptor* was later incorporated (Novas et al. 2009, supplementary information). This dataset is composed of 251 characters scored across 71 taxa. Three new characters were added, which are explained below. For a complete list of characters and data matrix see Turner et al. (2007, supplementary information) and Novas et al. (2009, supplementary information).

#### Heuristic tree search and results

The cladistic analysis was conducted through TNT 1.1 (Goloboff et al. 2008). The analysis of this dataset resulted in 190 MPTs. A heuristic search was performed with a hundred replications using the TBR branch swapping algorithm starting from Wagner MPTs. The resulting MPTs were subject to a final round of TBR branch swapping algorithm resulting in 1404 most parsimonious MPTs with a best score of 888 steps.

**Figure S1:** strict consensus of the resulting trees:

## **NEW CHARACTERS ADDED TO THE LIST PUBLISHED BY TURNER ET AL. (2007):**

Three new dental characters were incorporated to the list, which are the following:

Character 252: striations on the labial and lingual sides of the crown: absent (0) or present (1). *Striated crowns are here considered as the presence of two or more longitudinal grooves on the labial and/or lingual sides of the crown. Single grooves, such as those present in the teeth of Sinornithosaurus are not considered as striations.*

Character 253: basal cross-section of the maxillary and posterior dentary teeth crowns oval to sub-quadrangular (0) or sub-circular to circular (1) or figure-eight shaped (2). A *sub-quadrangular to oval crown cross-section is considered as such when the mesial-distal axis is larger in magnitude with respect to the labio-lingual axis of the teeth, whereas a sub-circular to circular crown section is referred to the case in which the mesial-distal axis is similar or equal to the labial-lingual axis of the teeth.*

Character 254: ratio between the highest tooth crown of the maxilla or the dentary and the height of the maxilla at level of the anterior rim of the antorbital fenestra: 0.010 to 0.10 (0), 0.10 to 0.20 (1), 0.20 to 0.30 (2), 0.30 to 0.40 (3), 0.40 to 0.50 (4). *Here is considered the maxillary or dentary teeth because they are generally the larger of the dental row. On the other hand, it is better to consider the height of the maxilla at the level of anterior limit of the antorbital fenestra because this area is one of the most generally preserved in the maxilla. Was avoided compared with the height of the dentary because in many taxa the height of this bone is very variable along its anteroposterior extension.*
