

Palynological characteristics of the Neogene of Western Poland

Maria Ziembińska-Tworzydło

Acta Palaeontologica Polonica 19 (3), 1974: 309-432

Palynological analysis of deposits ranging from the Middle Oligocene through the Upper Miocene from borings in the Great Poland Lowlands is presented. Main climatic-floristic phases on the territory under study have been characterized on the basis of the results of palynological analyses. A permanent tendency has been found to eliminate successive warmlike components of flora in younger warm phases of the Neogene. Descriptions of 174 species of sporomorphs are given. A new genus, *Iteapollis* and a new species *Microfoveolatisporis minutus* and several new combinations have been erected by the present writer.
